Introduction to Data Analysis With R

Gladstone Institutes

Krishna Choudhary
Bioinformatics Core, GIDB

June, 2020

Contents

- Motivation
- Hands-on work in RStudio
- Exercises
- Conclusions

R topics covered

- RStudio interface.
- Addition, subtraction, basic math operations.
- Assigning values to variables.
- Commenting in a script.
- Logical operators.
- Intro to functions and libraries.
- Reading data.
- Troubleshooting error messages.
- Exploring data. (Basic summaries such as mean, median, etc.)
- Selecting subsets of data.
- Plotting data.
- Data structures available in R.

R:= A calculator with more “buttons” than you will ever use.

- R can do all that a calculator can.
  - Open R.
  - Try 2+3.
  - Try 2*3.
  - Try (2+3)/5.
- Conclusion: Off with the calculators!

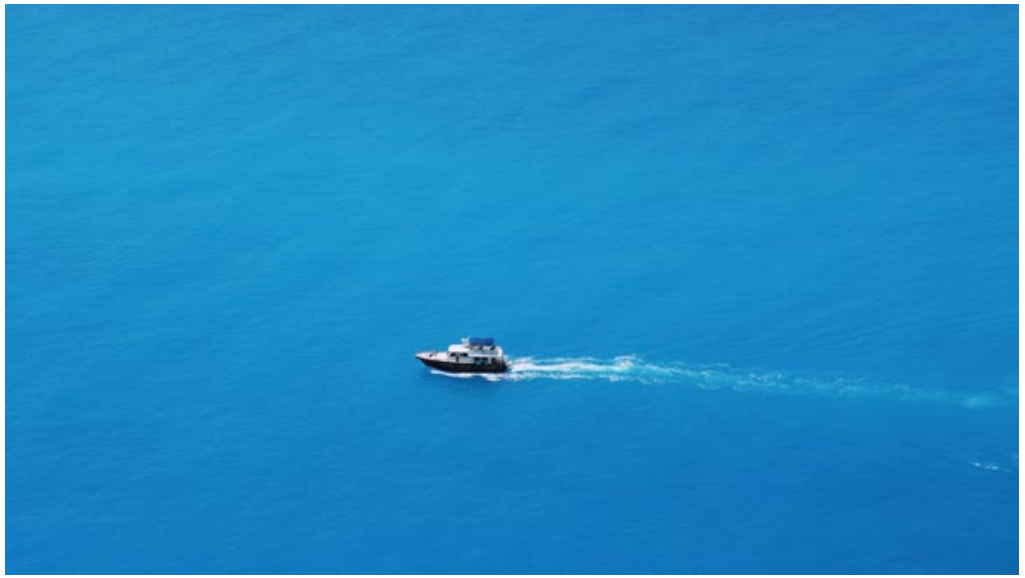
What is R?

- Collection of “buttons” that will perform mathematical calculations when pressed
  - The way to press “buttons” in R is by writing a command. Examples:
    - sum(2, 3)
    - prod(2,3)
    - sqrt(4)

- Links for useful R commands:
  - https://www.calvin.edu/~scofield/courses/m143/materials/RcmdsFromClass.pdf
  - https://www.personality-project.org/r/r.commands.html
  - https://www.rstudio.com/wp-content/uploads/2016/10/r-cheat-sheet-3.pdf

Excel: A boat to explore the surface of “Data-lantic ocean”.
R: A submarine for deep exploration.

Excel



R

R offers a lot more than Excel.

Excel

- Familiarity.
- Simple visualizations only.
- Simple statistics only. Limited support for advanced needs.
- You know it's falling short. That's why you're here.
- Pay for an inferior option. Why?

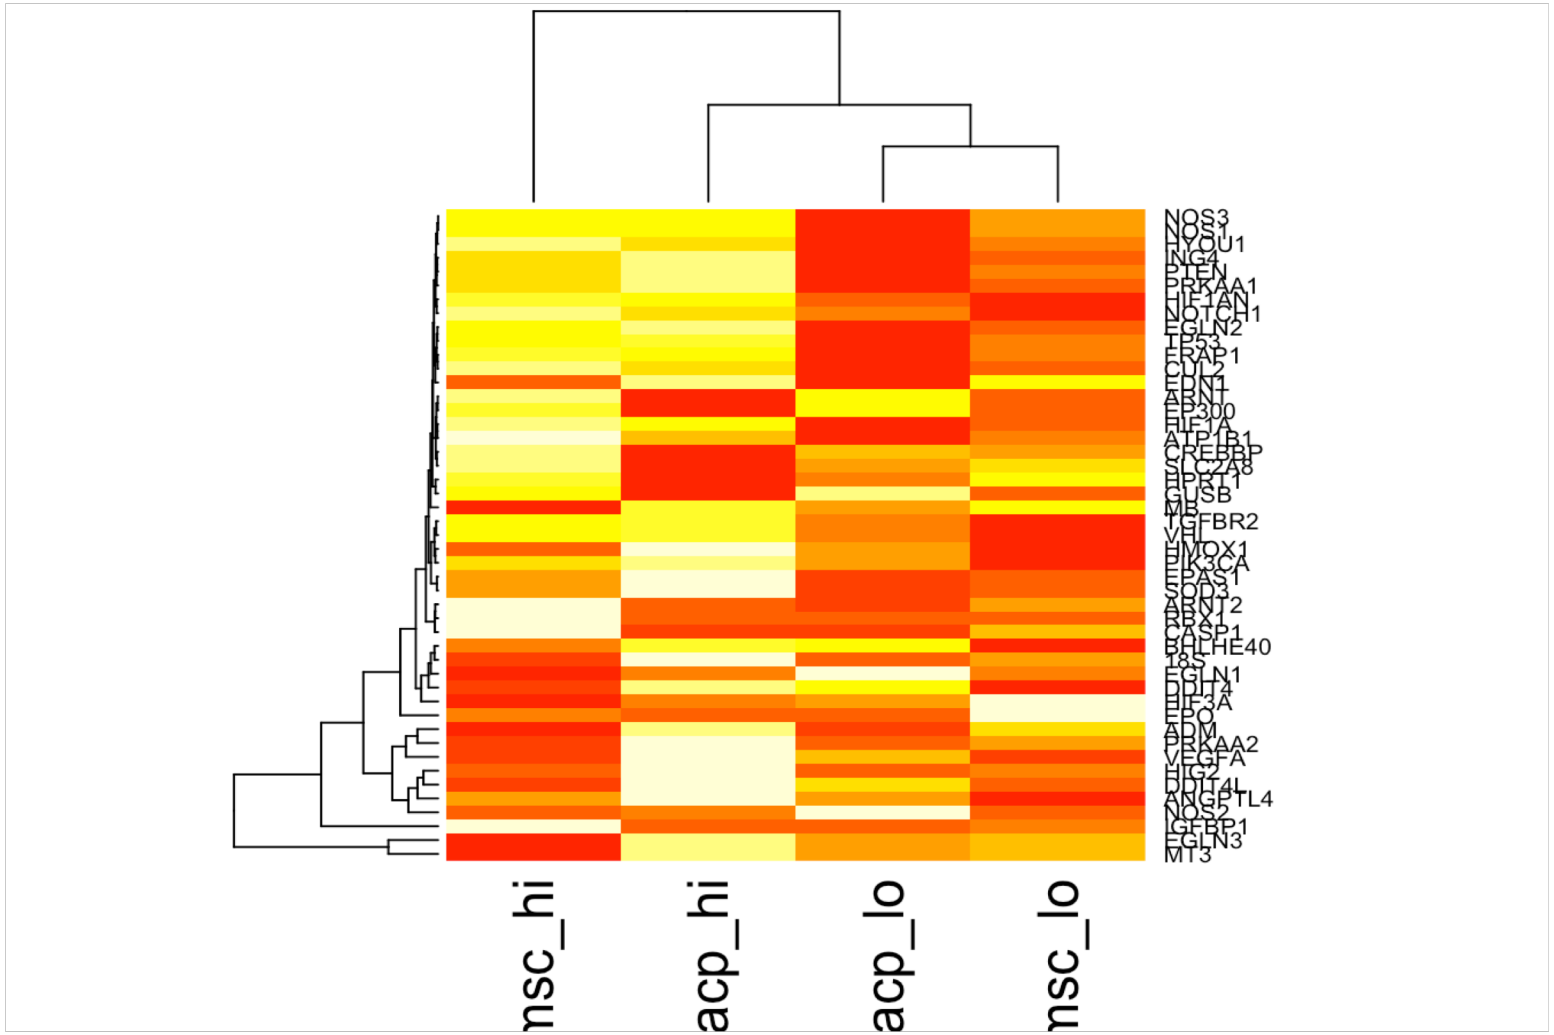
R

- Unknown territory.
- Visualization heaven.
- If there is a statistical method out there, you'll likely find it in R. All you need is to "hit a button".
- You will need it ever more.
- Free of cost.

R: designed specifically to support variety of biological data analysis.

- Bioconductor: Software for all kinds of biological data.
  - Understands file formats commonly used in biology.
  - Vetted by large community of users.
  - Frequently updated.
  - https://www.bioconductor.org/

R: easy visualization of biological data. Supports interactive visualization.



R: Increasingly becoming more central to biology.

- Biological software tools are being integrated with R.
- Upcoming training workshops may require R.

R vs Python: depends on what we need

- https://www.datacamp.com/community/tutorials/r-or-python-for-data-analysis
  - R is used by statisticians, engineers and scientists.
  - Python is popular among developers and programmers because it is faster.
  - R is primarily used in academics and research. Also common in industry for bioinformatics.
  - Unique attractions of R: ggplot2 for data visualization, Bioconductor

RStudio and basic arithmetic.

R is a console application.

- Text only interface. Inputs and outputs can be images.

- RStudio: Brings more Graphical User Interface (GUI) features to R.
  - RStudio is to R as Microsoft Word is to Notepad in Windows or TextEdit in Mac. (~kinda)

- Launch RStudio.
- Try from these:
  - sum(2,3)
  - prod(2,3)
  - sqrt(5.5)

Commenting inside a source script

- Looking at an old script, or someone else's script can be scary.
- Speak to machine in code.
- Leave comments in natural language (e.g., English).
  - Anything written after # is interpreted by R as a comment for humans.

Assignment *operators* in R

- Results of one calculation may be input to another.
- Save intermediate results by assigning them to variables.
- a <- sum(2,3)
- a = sum(2,3)
  - Variables store values.
  - Called so because they can be assigned any value.

- Both work but prefer to use ‘<-’ for now.

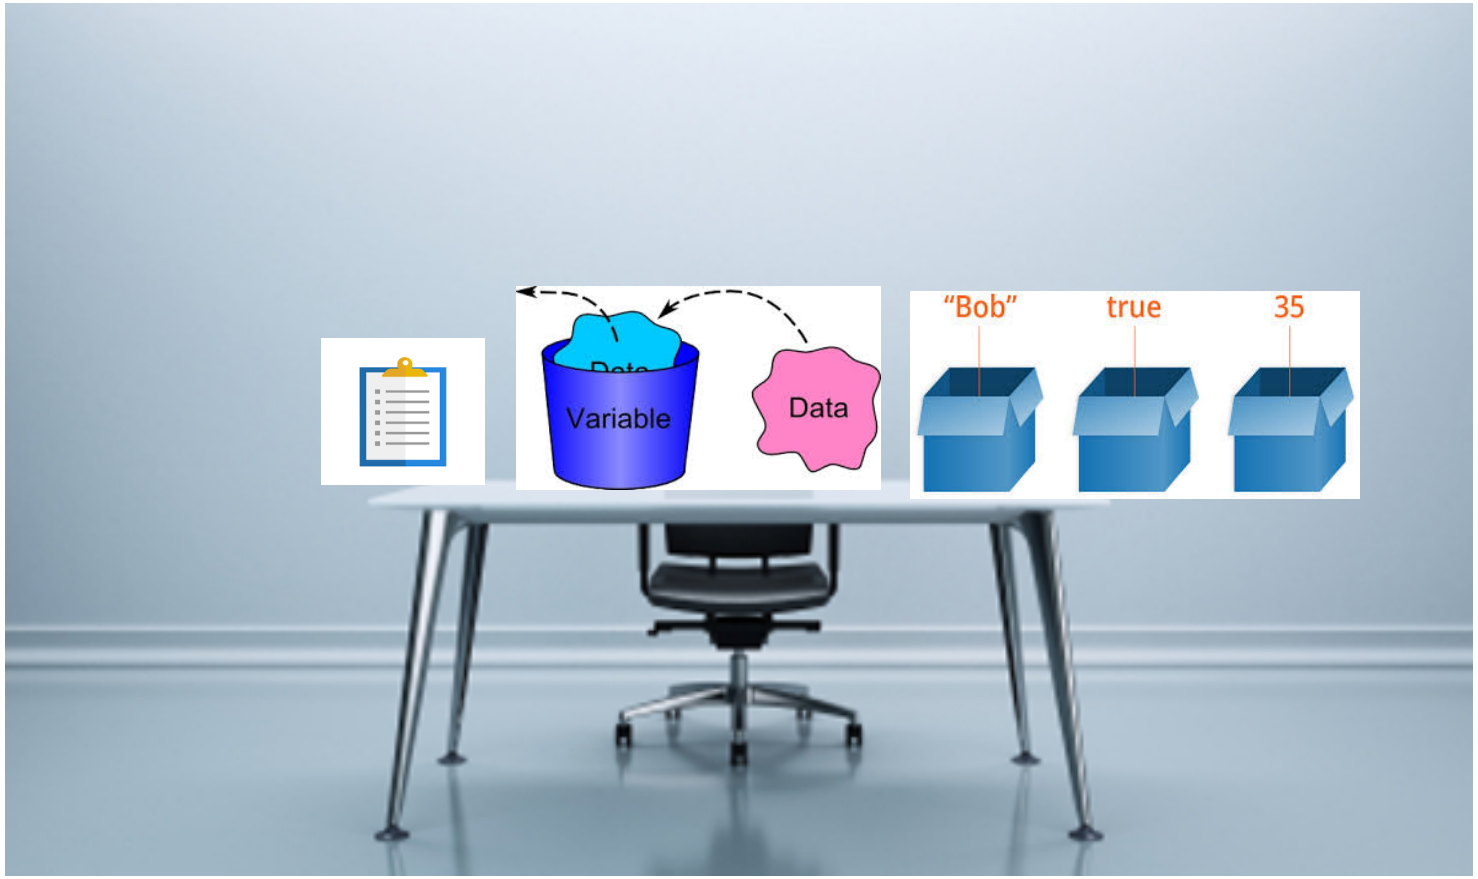
- Change ‘=’ to ‘<-’ in the script and rerun.

Rules for naming variables

- Names can be a combination of letters, digits, period (.) and underscore (_).
- It must start with a letter or a period. If it starts with a period, it cannot be followed by a digit.
- Reserved words in R must not be used as variable names.

Empty workspace/environment

Data analysis creates objects that store data.
(top-right pane in RStudio)



Scientific calculations may require checking criteria.

- Is p-value less than 0.05?
- Is organism named *Homo sapiens*?
- What percent of patients have heart rate greater than 130 bpm?

Scientific calculations may require checking criteria.

- Is p-value less than or equal to 0.05?
  - p <= 0.05
- Is organism named Homo sapiens?
  - name == “Homo sapiens”
- What percent of patients have heart rate greater than 130 bpm?
  - bpm > 130

Might need to check multiple criteria simultaneously.

- p <= 0.05 & bpm > 130
- bpm == 120 & name == “Homo sapiens”

Useful *operators* in R

- ! means ‘NOT’
- != means ‘NOT EQUAL’
- == means ‘EQUAL’
- & means ‘AND’
- | means ‘OR’

Thus far…

- R console
- Source scripts
- Commenting
- Environment
- Simple calculations
- Variables

Coming up…

- Intro to functions and libraries.
- Reading data.
- Troubleshooting error messages.
- Exploring data. (Basic summaries such as mean, median, etc.)
- Selecting subsets of data.
- Plotting data.
- Data structures available in R.

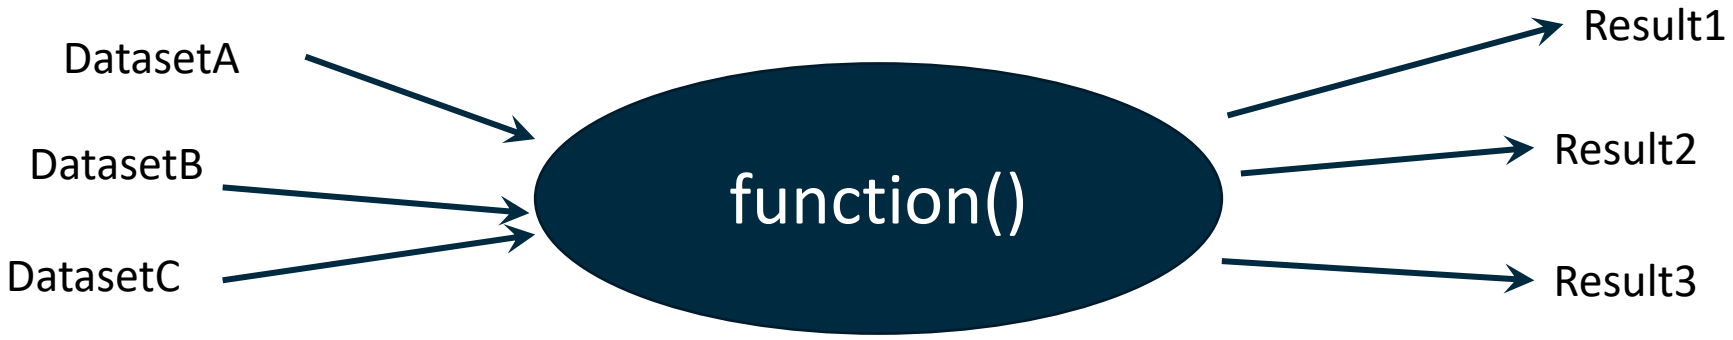
Functions

Working with buttons for modern scientific calculations?

- The best of calculators => 10s of buttons for specific tasks.
- Modern science needs many times more than 10s.

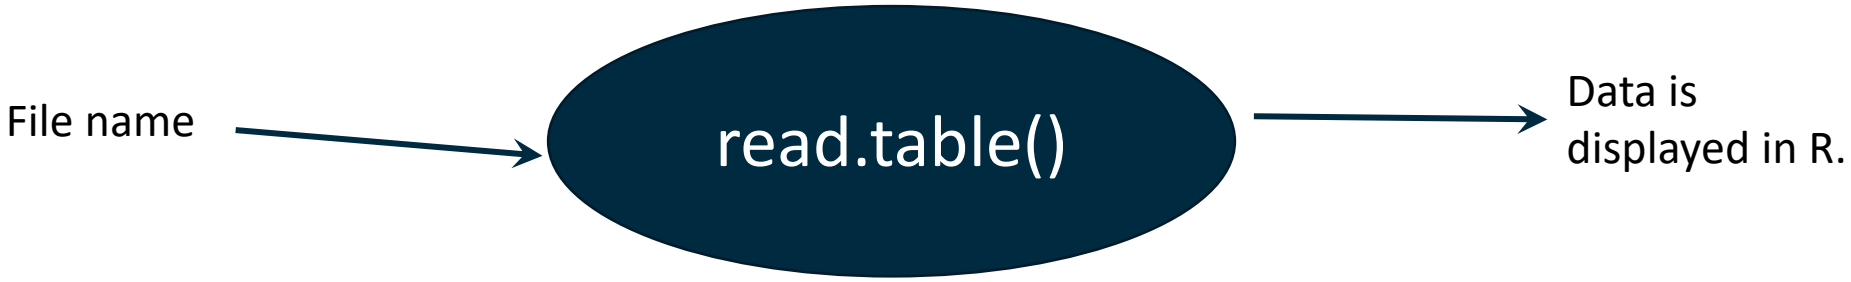
Functions are to R what buttons are to calculators.

- R can perform 100s of 1000s of tasks.
- Tasks are performed by using functions.
  - Examples: sum(), prod(), mean(), t.test().



There are functions for all sorts of things.

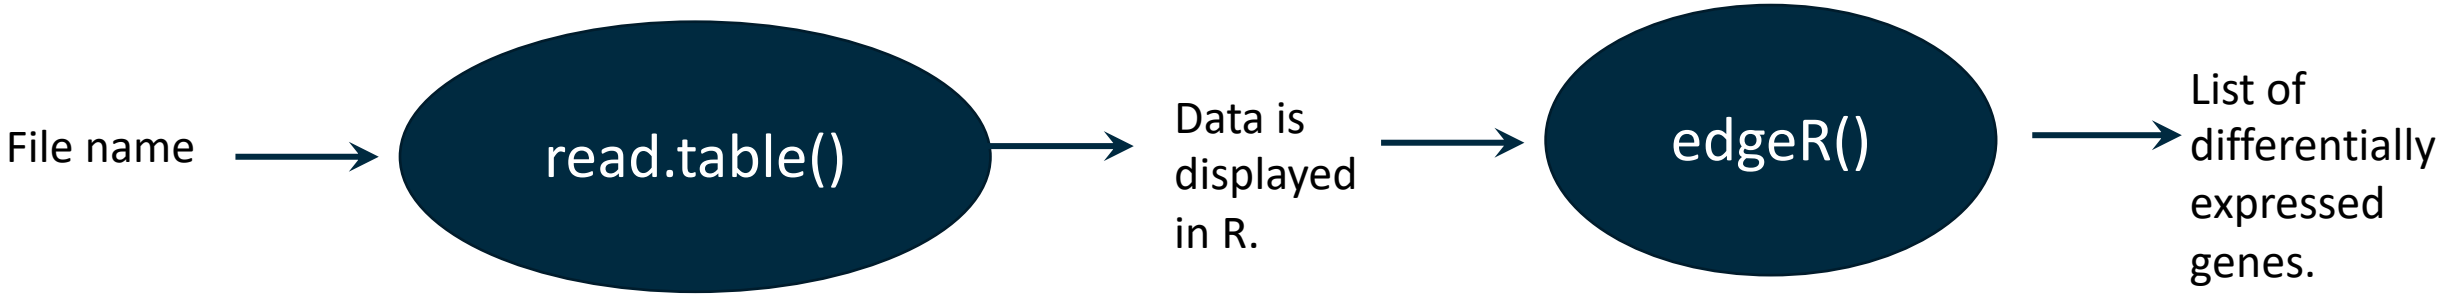
- Example to read a table saved in a file:
  - read.table()
  - Usage: read.table(“filename”)



There are functions for all sorts of things.

- Example to find complementary DNA sequence.
  - complement()
  - Usage: complement(sequence)

Directing output of one function as input to another.



Library is a collection of functions.

- R works with > 100000 functions.
- More being added everyday.
- If the software were to load (i.e., make available) all of them at startup, it will take a while to launch.
- Solution: Bundle related functions together in a *library.*
  - Example: edgeR.
- Load functions only when needed. (:= Install apps on smartphone as needed)

Functions may need lots of information

- Calculators may take only numbers.
- R functions take variety of things. Numbers, characters, etc.
- Example:
  - Reading a file. Inputs required: File name and address on computer, formatting of file, type of file, etc.
  - Writing a file. Inputs required:
    - what to write?
    - where to write?
    - how to format the file?
    - Include column names, row names?
    - separate with comma?

Reading a data file.

There are functions for all sorts of things.

- Functions to read files:
  - read.csv()
  - read.table()
  - read.xlsx()

- Try reading a file called “iris.csv”
  - read.table(file = “iris.csv”)

Error!!!

WHAT IF I TOLD YOU
I COME IN PEACE, AND I AM NOT YOUR ENEMY
megenerator.net

How to find help?

- Execute a command name with the question mark before it. Example:
  - ?read.table

- Read the error message!
  - Often, no need to understand every word.
  - Look for key words in error message.

- Copy-paste the error message verbatim in Google!

We need to set directory to where the file is.

- The function for this is:
  - setwd()

- Can also do it interactively using the menu bar.
  - In RStudio: Session -> Set Working Directory -> Choose Working Directory.

- Verify using
  - getwd()

Working with a dataset

(Read, Subset, Visualize)

Reading a dataset

- Function we will use: read.table().

- Dataset used: Iris dataset.
  - Iris is a plant genus.
  - Species of this genus may be identified based on the dimensions of petals and sepals of its flowers.

- Try read.table("iris.csv").
  - dat <- read.table("iris.csv")

Explore the current data

- View(dat) #Shows the data in a tabular format.
- dim(dat) #Shows the dimensions of the table, i.e. rows and columns.
- colnames(dat) #Shows the names of columns, if any.
- summary(dat) #Outputs summary statistics of data. Ex- minimum, max, median, etc.
- head(dat) #Displays first 6 rows of data.
- tail(dat) #Displays last 6 rows of data.

Extracting parts of data in another variable.

- spl_len <- dat$Sepal.Length
  - $ is used to refer to a feature in the data.
  - Check what spl_len is.
  - class(spl_len)

- It contains numbers, makes sense to call it “numeric”.

- spl_len is an ordered series of numeric values.
  - Ordered series of values are called vectors in R. (More on that later)

Another data type: *Factor*

- spcs <- dat$Species
  - Check what spcs is.
  - Factor variable.
  - spcs <- as.character(spcs)
  - spcs <- unique(spcs)
  - How to check if spcs includes sapiens?
    - “sapiens” %in% spcs

- Factors are used to represent categorical variables.

- spcs is now a character vector.

Goal: To extract subset of data for *Iris setosa*.

- which_setosa <- dat$Species == “setosa”
  - dat$Species == “setosa” compares each value in dat$Species with character “setosa”.
  - If a value equals “setosa”, output is TRUE.
  - Check what which_setosa is. (a logical vector)

- To extract the subset for *Iris setosa*:
  - dat_setosa <- dat[which_setosa,]

Goal: To extract subset of data for *Iris setosa*.

- Alternatively
  - dat_setosa <- subset(dat, Species == “setosa”)
  - If only I had googled!!

- Wishing you could just hit enter?
- Feeling like a lot of people would want it?
- Google!

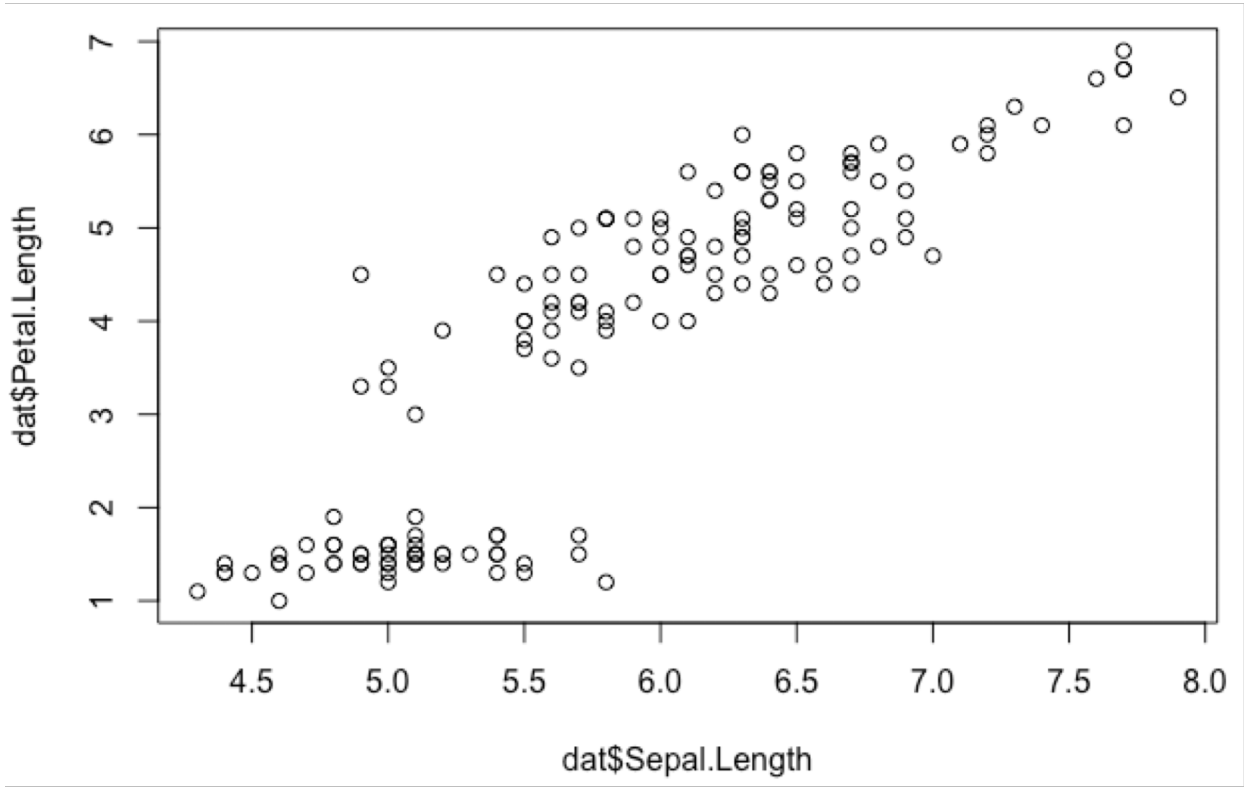
- TRUE for most anything at a beginner level.
- If you get an error, someone else would have got it too. Google!

Basic statistics.

- Mean
  - mean(dat$Sepal.Length)
- Median
  - median(dat$Petal.Length)
- Standard deviation
  - sd(dat$Petal.Width)
- Histogram
  - hist(dat$Sepal.Width)
- Boxplot
  - boxplot(dat$Sepal.Length)

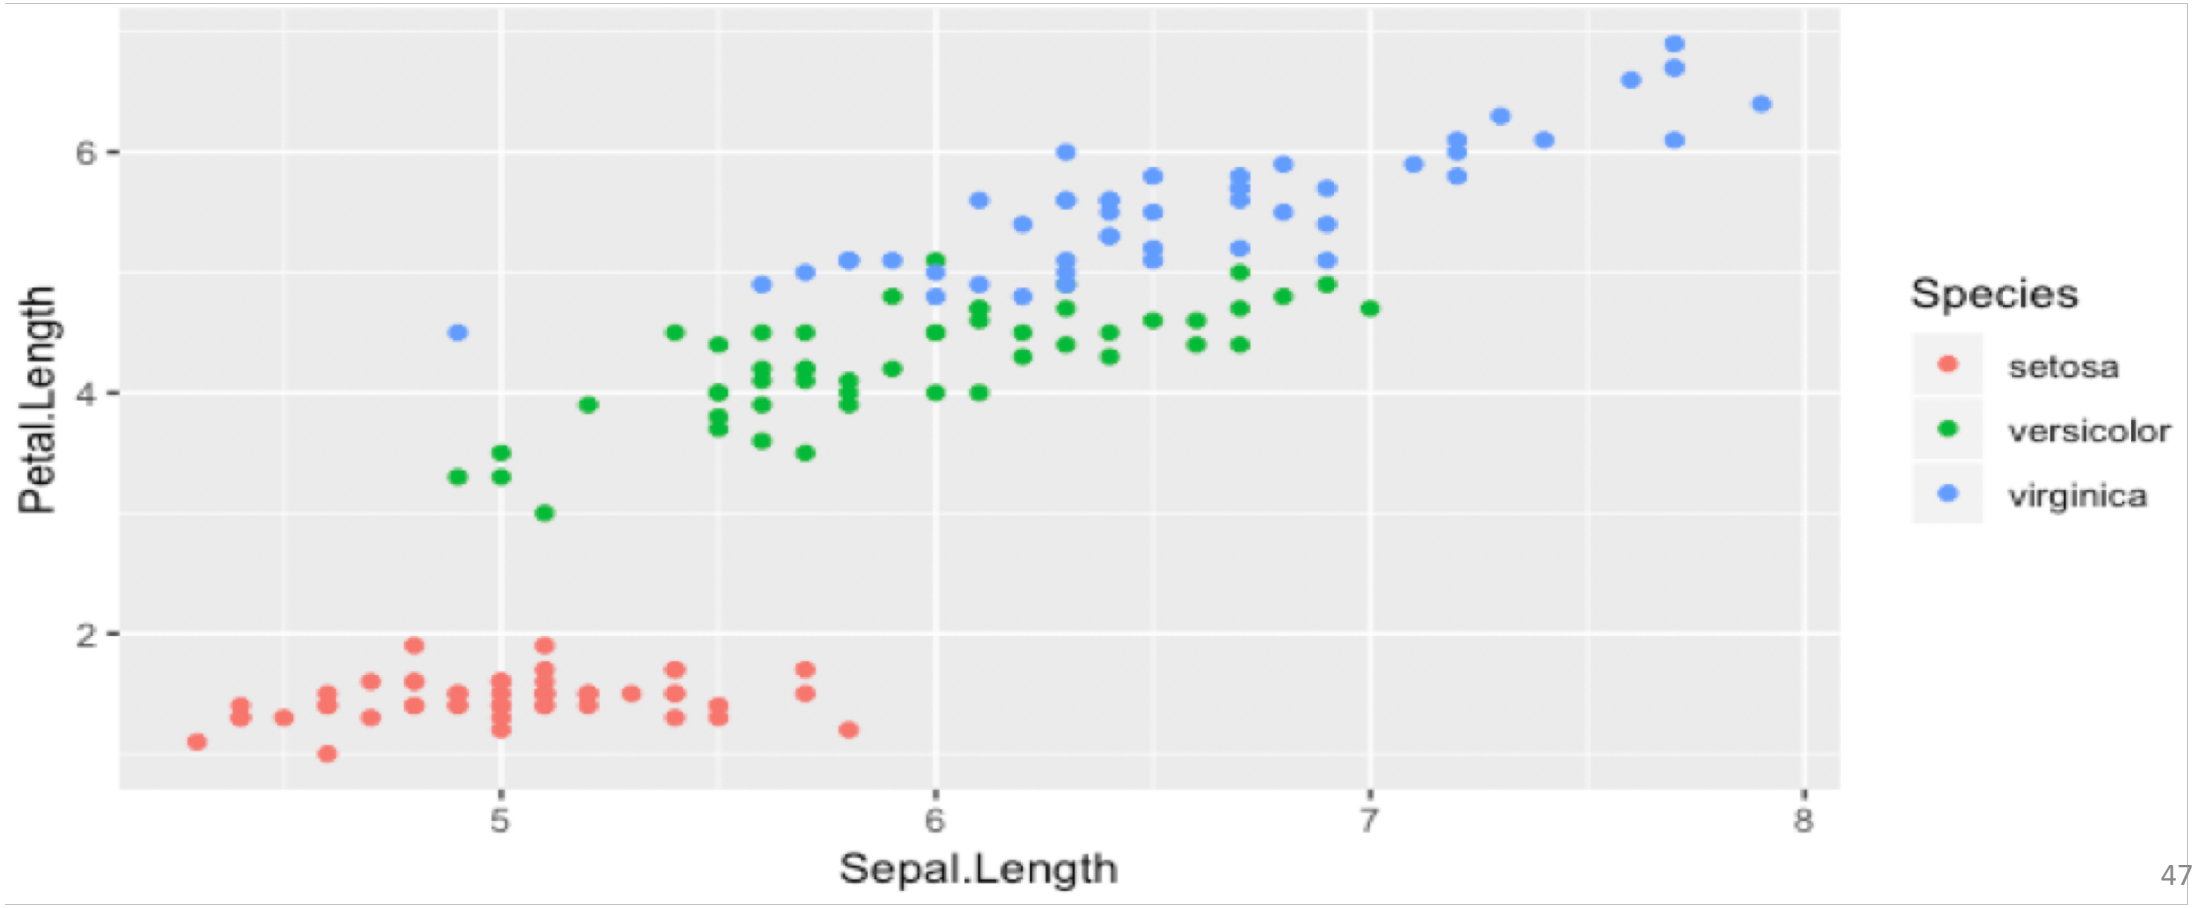
Visualizing data.

- plot(x= dat$Sepal.Length, y = dat$Petal.Length)



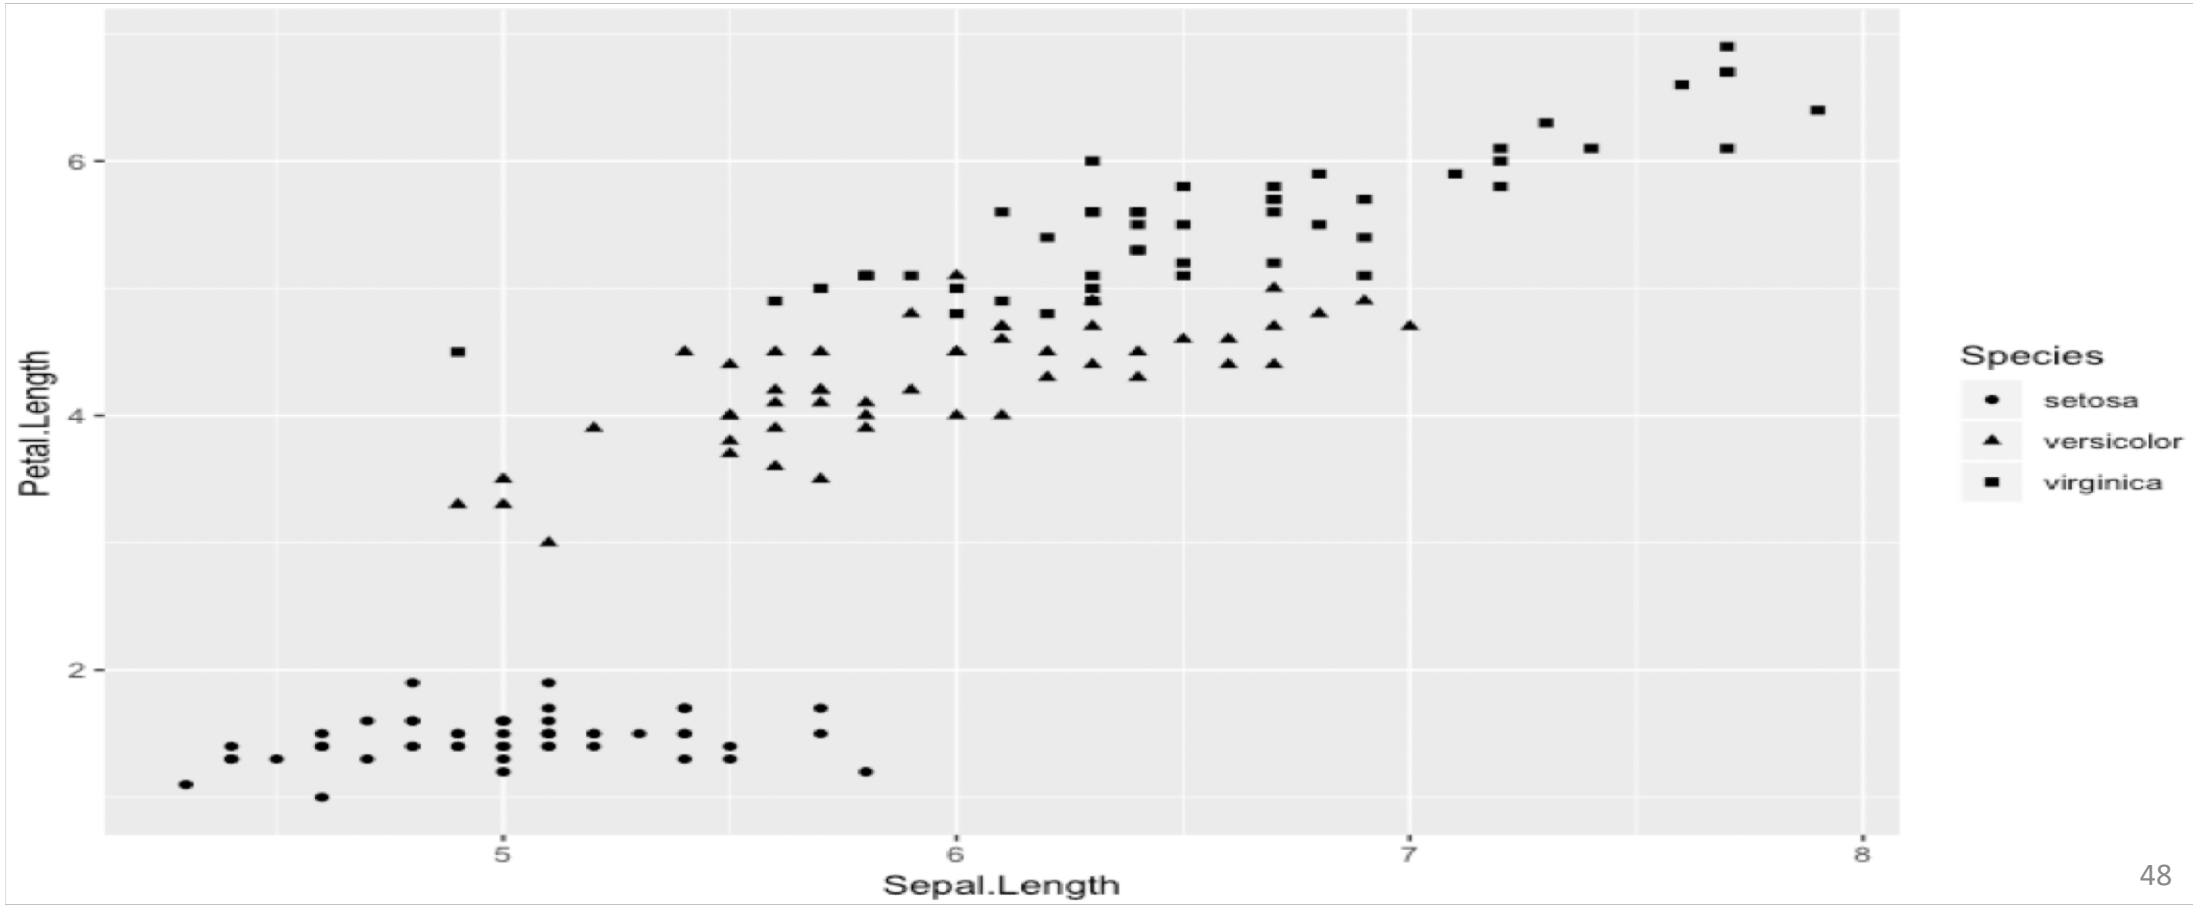
Visualizing data.

- qplot(x = Sepal.Length, y = Petal.Length, data = dat, color = Species)



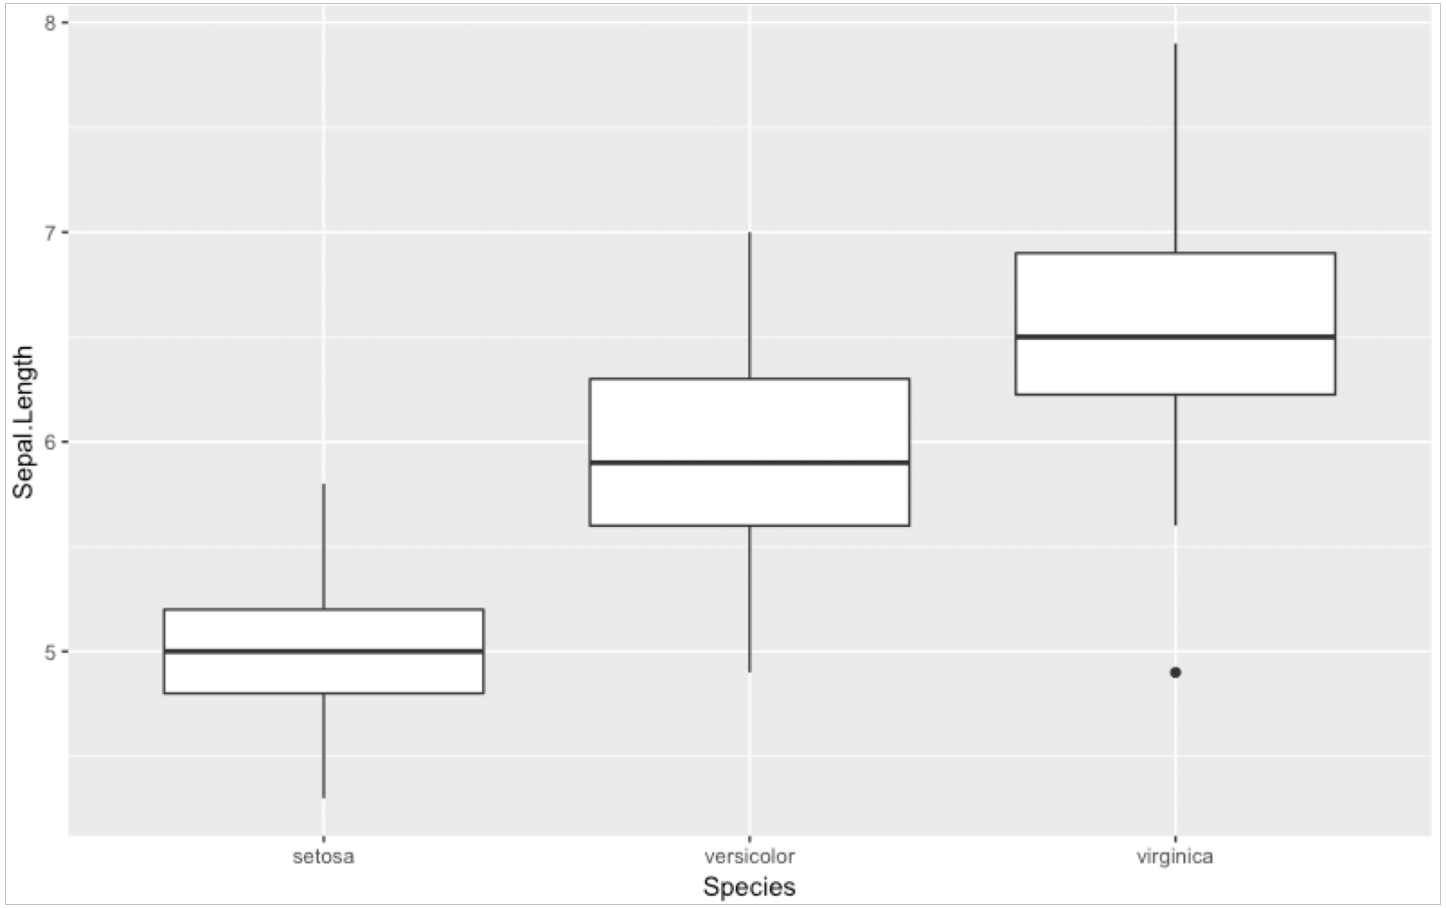
Visualizing data.

- qplot(x = Sepal.Length, y = Petal.Length, data = dat, shape = Species)



Visualizing data.

- qplot(x = Species, y = Sepal.Length, data = dat, geom = "boxplot")



Loops and conditional statements.

Loop over rows in a tabular data

- table <- read.table(“iris.csv”)
- for (row in table) {

  #Do some calculation for each row

  ...

  …

  }

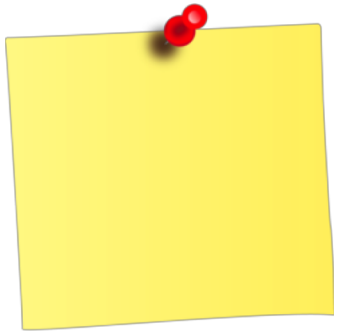
Conditional statements

- if (p < 0.05) {
  print(gene_info)
  …
  } else {
  print(gene_name)
  }

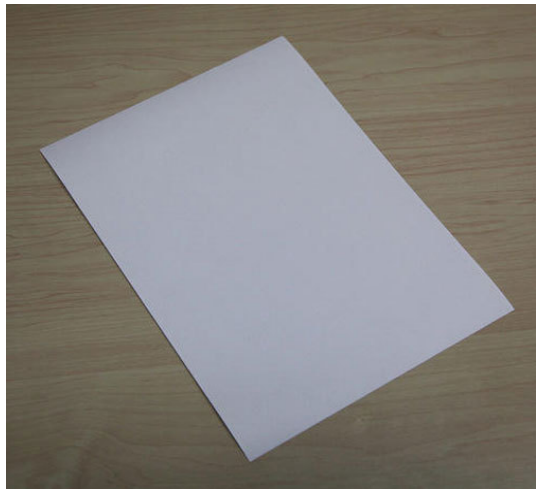
Data structures.

Data structures are data organization/storage formats.

- Storing data physically? Options:



Sticky note



Printer paper

Task pad

Long scroll

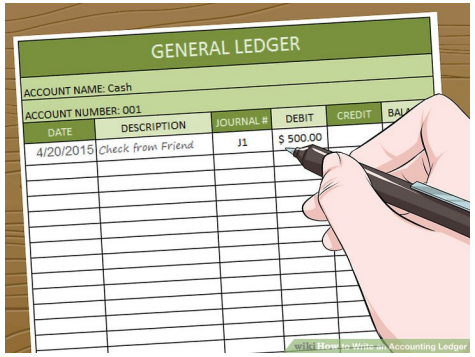
Data structures are data organization/storage formats.

- Working with data in R? Options:
  - Numeric vector
    - c(2, 5, 10, 11)
  - Character vector
    - c(“apples”, “oranges”, “butter”, “dry yeast”)
  - Data frames
    - dat from Iris example.
  - Matrix
    - Example counts for genes in several samples.
  - Lists
    - Flexible data structures.
    - mylist <- list(a = c(2, 5, 10, 11),
      b = c(“apples”, “oranges”, “butter”, “dry yeast”)
)

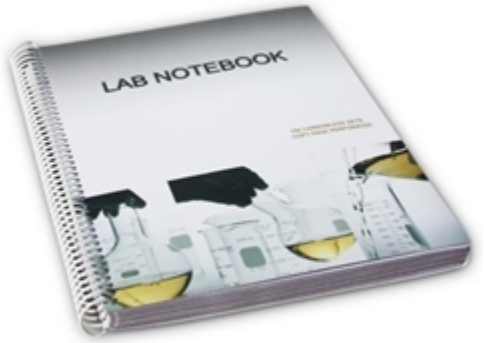
Data structures for special needs?

- Storing data physically? Options:

Sheet music



Ledger



Lab notebook

Data structures for special needs?

- Working with data in R?
  - Packages may have author-defined data structures.
  - Example – DGEList defined in edgeR.
    - Stores counts, sample grouping information, normalization factors, etc. in one place.

Exercise

Reading unclean data.

- “dirty_data.txt” contains data that is formatted differently.
- Figure out how to read it.
- Tips:
  - Error message comes in peace. It is your friend!
  - Google!

Alternative file types

- Scientific studies may involve various kinds of files.

- Example:
  - FASTA files for sequences.
  - FASTQ files for sequencing reads.
  - SAM files for alignment.
  - GTF files for gene annotations.
  - Excel sheets with multiple sheets.

- Google for how to read FASTA file in R. (5 min)

How to read in FASTA files?

- Searching for packages returns:
  - seqinr
  - Biostrings
  - …

- Example with seqinr
  - install.packages(“seqinr”)
  - library(seqinr)
  - read.fasta(“16S.fasta”)

- Check options available with read.fasta.
  - ?read.fasta

Recap of R topics covered

- RStudio interface.
- Addition, subtraction, basic math operations.
- Assigning values to variables.
- Commenting in a script.
- Logical operators.
- Intro to functions and libraries.
- Reading data.
- Troubleshooting error messages.
- Exploring data. (Basic summaries such as mean, median, etc.)
- Selecting subsets of data.
- Plotting data.
- Data structures available in R.

Your feedback is important to us!

- https://bioinformatics-course-feedback.questionpro.com/
- ~3 min.

Possibilities

Detailed high resolution graphics : Examples

- https://www.r-graph-gallery.com/

Bioconductor for biological data analysis

Packages	Uses
edgeR, DESeq2, limma, voom	Differential gene expression analysis
phyloseq, microbiome	Microbiome data analysis
rWikipathways, KEGGgraph	Pathway analysis
MSstats	Proteomic data analysis
bsseq, methylKit	DNA methylation analysis
chipseq	ChIP-Seq data analysis
CRISPRseek, gCrisprTools, CrispRVariants	CRISPR related data analysis

Conclusions

- R is a “smart” version of calculators.
- Error message comes in peace.
- Google!

Upcoming workshops

- Intro to RNA-seq data analysis (March 24 and 26)
- Intermediate R: Data visualization (April 7 and 9)
- Intermediate RNA-seq data analysis (April 28 and 30)
- Intro to Unix command line (May 5)
